COMPANY PRESENTATION

1.1 Field of activity

1.1.1 Wind energy

Upteko has been manually inspecting wind-turbines since 2018. Today, they are using this data and knowledge to build a system to automatically inspect wind turbines. Upteko's autonomous drone system will provide high-quality aerial data for all inspections and maintenance requirements, in a safer, more efficient manner, without causing operational downtime. Their drones are pre-programmed with geo-referenced 3D trajectories for the inspection of wind turbines. While flying the planned routes, several images are acquired. The actual number depends on the camera specification, flight altitude and post-processing performance (overlap between images). All images are georeferenced using the UAV position at the acquisition time and these images are afterwards stitched together and in one picture on which the locations of the damages are shown. They deliver these data as per the clients' requirements in raw files or provide a damage report that explains the severity of damages from type 1 to type 5.

1.1.2 Oil and Gas

Upteko is working on a solution for detecting oil spills on the surface of the water. They are developing payloads for their drone system that can help detect the signature of oil floating on water surfaces. This payload can be installed on Lärke and can be used to automatically or manually detect oil spills. Upteko have developed an application to detect pirate attacks on off-shore oil rigs and large commercial ships. Pirates use small ships to attack these oil rigs and large commercial ships at night. They take the crew and contents hostage. There are no mobile long-range detection tools with aerial insight to give the crew information about nearby pirates. This results not only in huge loss to the

oil industry but also endangers the crew at huge life risks. The total cost of piracy to the shipping industry, from insurance and time lost, is estimated at over €6B/year. Upteko's multipurpose drone system has a feature called perimeter control. This feature allows any member of the crew to investigate surrounding vessels approaching the premises. A built-in feature within the drone system is added to allow a crew member to operate and control the aerial camera in any direction with no prior drone experience. The geothermic cameras and the infrared sensors help to detect the approach of any pirates faster even during night-time.

1.1.3 Offshore and Maritime

Upteko has been consistently involved with the maritime industry since its inception. They are developing a drone system solution to live on the ship, to connect port operations on the ground and at the sea, with insight from the sky. This system includes a drone and a charging station for the drone that will be installed on the ship. The drone can autonomously perform a variety of tasks and then fly back and charge its batteries while staying protected against the weather. With an in-depth understanding of the challenges that the maritime industries face in attempting long and expensive inspections and other operational tasks, Upteko's software and hardware drone system allows a 100% automatic inspection of a ship in less than 2 hours. Having a permanent drone on a ship will be extremely helpful in a number of cases that can range from Search and Rescue (SAR) operations, vessel docking, dry dock inspections, fire hazard detection and situational awareness among other functionalities.

1.2 History

Upteko™ was founded in 2018 by Mads Joergensen, Benjamin Mejnertz, and Sebastian Duus to pursue the opportunity of developing drone applications for the maritime sector. For Benjamin and Sebastian, it started as a hobby, competing in RC Helicopter competitions around the world and later became a business worth pursuing. Mads came onboard, and together they created Upteko and built a great team of experienced drone pilots, software- and hardware engineers, and business developers. Today Upteko has offices located in Copenhagen, Odense, and Skanderborg. Upteko is about using their creativity and initiative to become leaders in the drone industry. To develop fitting so-

lutions to your needs, they value collaboration and co-creation highly among external parties. Through several years of collaborating with their customers, complementary assets providers, and even competitors, they have achieved priceless partnership within the maritime and other sectors. They are continuously on the hunt for new collaborations.

1.3 Legal and social model

In Denmark, most companies operate under a legal structure of a private limited company (Anpartsselskab, ApS) as Upteko. The country has strong social welfare systems and labor laws, which mandate fair treatment and protection of employees. Danish companies usually have a strong focus on maintaining a healthy work-life balance and uphold high ethical standards, both socially and environmentally.

1.4 Economic model

Denmark follows a mixed-market capitalist system, combining free market principles with a strong regulatory oversight. Upteko operates under a model of sustainable growth, focusing on long-term stability rather than short-term profits. This includes social responsibility, ethical business practices, and environmental sustainability.

1.5 Type of work organization

Denmark has a distinctive workplace culture, often characterized by a flat organizational structure. This implies low power distance, high levels of trust, and extensive collaboration between different levels of the organization. Danish companies typically have strong communication and decision-making practices, promoting employee empowerment and autonomy. Upteko is organised in three main sectors : **Technical Development** , **Finance** and **Product management** . Here is the actual organization chart of the company :

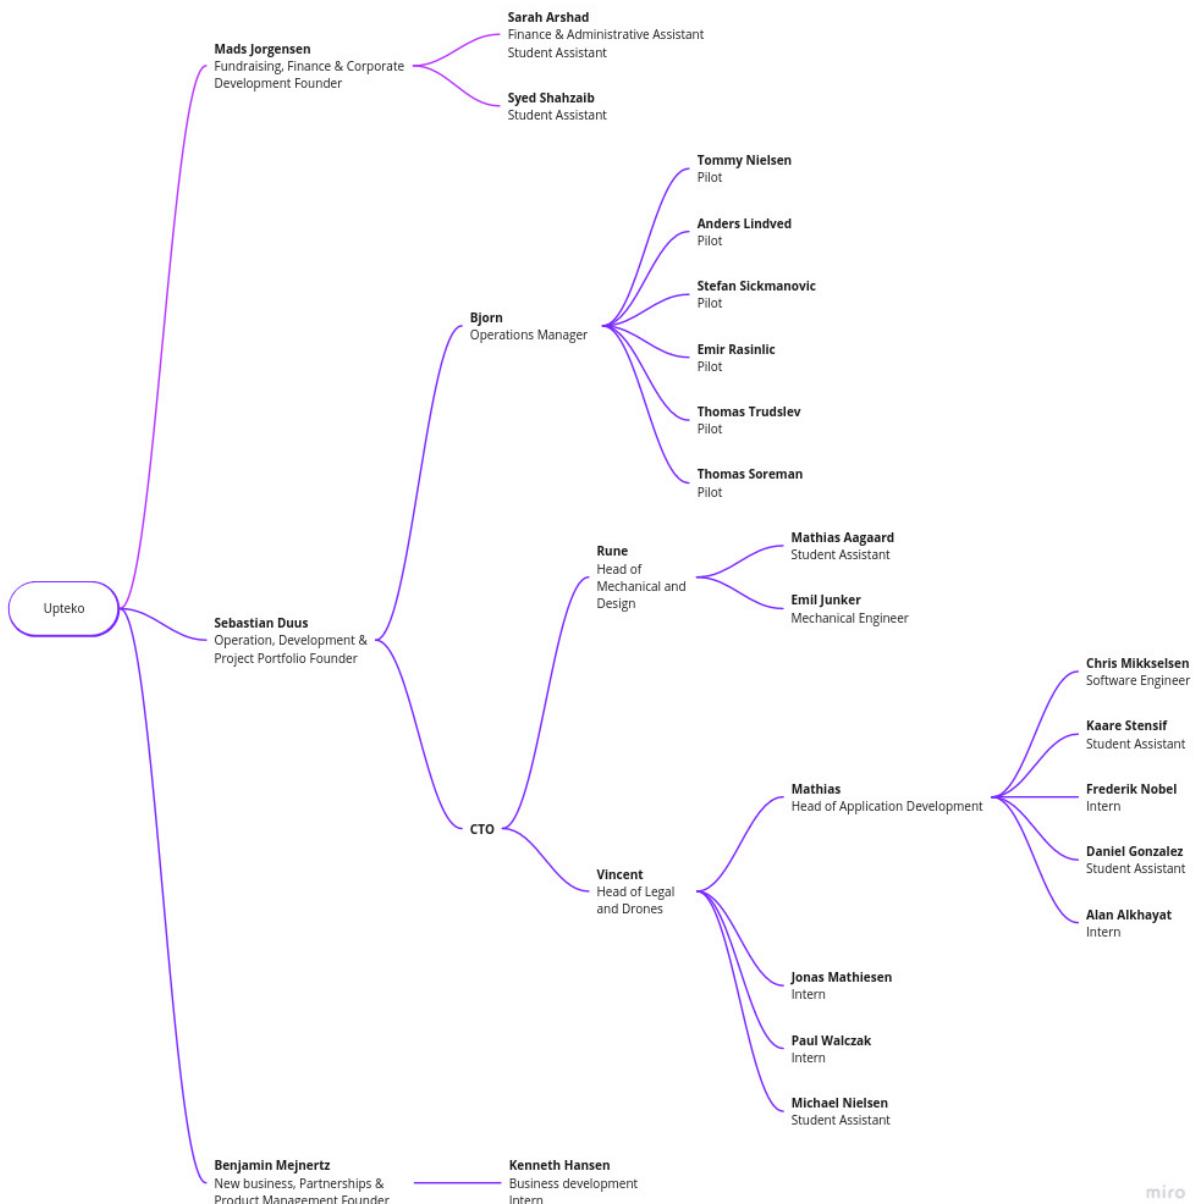

Figure 1.1 – Upteko company organization chart

PROJECTS

2.1 STM32 IMU

2.1.1 PModNav

The purpose is to get the `roll`, `pitch` and `yaw` from the PModNav to plot a 3D visualization of the IMU. The final purpose of it is to create log files from the orientation and attitude of the drone in real-time. By combining data from accelerometers, gyroscopes and magnetometers, an IMU can provide information about the object's position, orientation and angular velocity. This is crucial for tasks such as safety deployment or drone tracking. The STM32-L4796ZG recovers the value of the sensors from the `PModNav` via `SPI Bus` and transmits them to the HMI via `UART` connection.

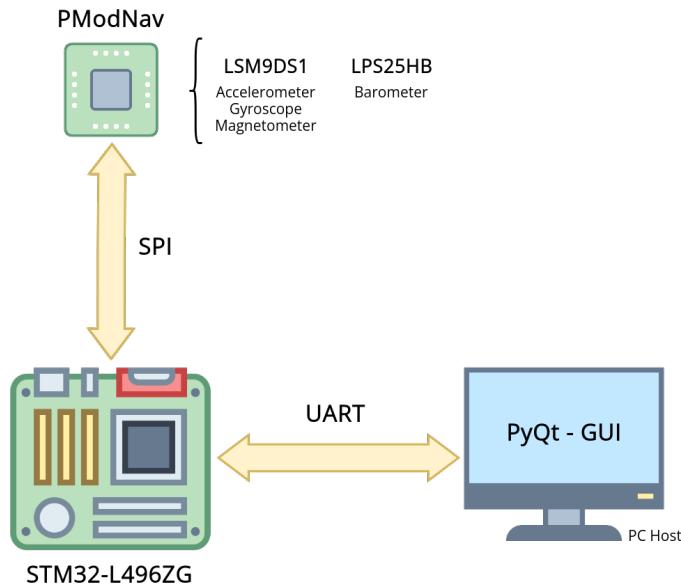

Figure 2.1 – Project communication overview

2.1.1.1 Hardware

The PModNav module is equipped with the [LSM9DS1](#) [1] sensor, offering 10-Degree Of Freedom (DOF) functionality. It integrates a 3-axis accelerometer, 3-axis gyroscope, 3-axis magnetometer, and an LPS25HB digital barometer. This comprehensive sensor suite allows users to obtain orientation-related data and determine the precise position and heading of the module. The module supports various full-scale options for linear acceleration, angular rate, and magnetic field measurements. It follows the Digilent Interface Specification Type 2A and utilizes a 12-pin Pmod connector with an SPI interface.

2.1.1.2 Software and Development Environment

The development environment for the PModNav project is STM32 CubeIDE. The documentation references project sources, including code snippets and libraries, such as the PModNav driver and Madgwick's filter implementation.

2.1.1.3 Data Processing

The project outlines two approaches for deriving object attitudes: Euler angles and quaternions. Euler angles are obtained through the integration of angular velocity and provide information about the roll, pitch, and yaw of an object. However, a challenge known as [Gimbal Lock](#) [2] arises when using Euler angles directly, resulting in a loss of a degree of freedom when two axes of rotation overlap. To overcome this, quaternions are introduced as a mathematical representation of displacement and rotation. They effectively resolve the Gimbal Lock issue and provide a more robust solution for determining attitudes.

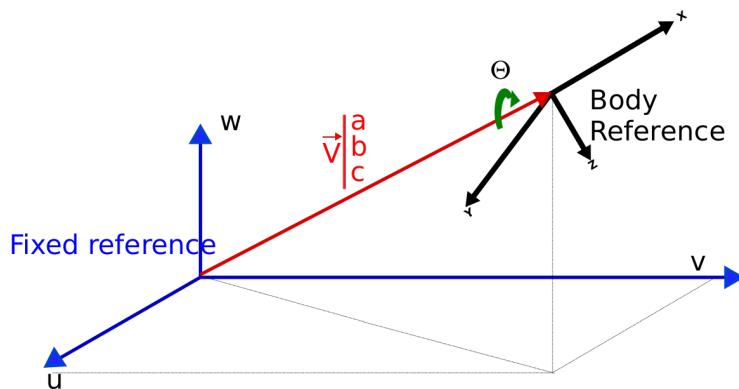

Figure 2.2 – Quaternion representation

$$Q = [q_0, q_1, q_2, q_3]$$

$$Q = \left[\cos\left(\frac{\theta}{2}\right), a.\sin\left(\frac{\theta}{2}\right), b.\sin\left(\frac{\theta}{2}\right), c.\sin\left(\frac{\theta}{2}\right) \right]$$

At each T_e , we can calculate the new value of the quaternion vector from the velocity :

$$Q_{k+1} = Q_k + \frac{1}{2} \cdot T_e \cdot \omega_k \cdot Q_k$$

For cheap IMUs, it is unavoidable to perform a data fusion to make the accelerometer compensate for the gyroscope defect. If using a Kalmann filter is possible, there are other (faster) algorithms like Madgwick's. The idea is to compensate for the gyroscope measurement error by modulating its values by the result of a comparison between an estimate of the gravity field and the measured gravity field (with the accelerometer).

Note: Only 6 DOF from the accelerometer and gyroscope have been used to this project due to too sensitive and hard to calibrate data from the magnetometer

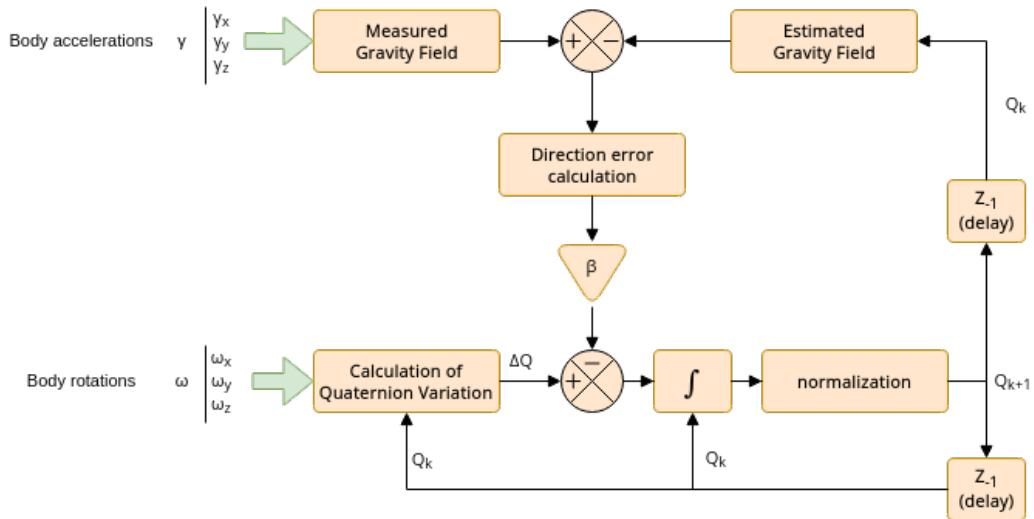

Figure 2.3 – Madgwick filter schematic

I decided to use the most popular open source algorithm to compute rotations, the

Madgwick's algorithm [3]. This calculation updates the quaternion, from which the attitudes (Euler angles) can be calculated.

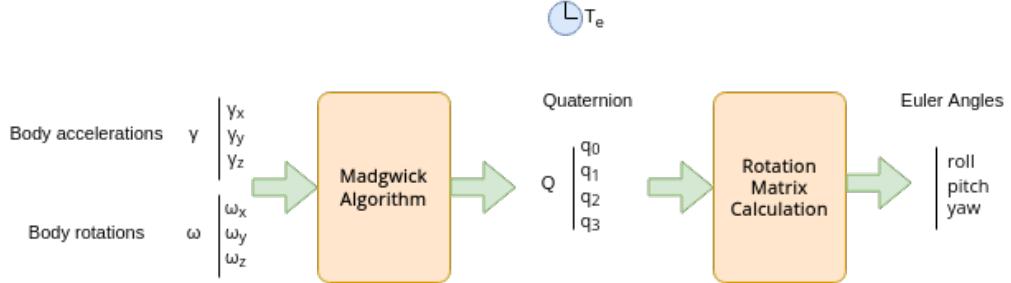

Figure 2.4 – Data transform schematic

Calculation of the Euler Angles from the rotation matrix :

$$\begin{aligned}
 R_{12} &= 2(q_1 q_2 + q_0 q_3) \\
 R_{22} &= q_0^2 + q_1^2 - q_2^2 - q_3^2 \\
 R_{31} &= 2(q_0 q_1 + q_2 q_3) \\
 R_{32} &= 2(q_1 q_3 - q_0 q_2) \\
 R_{33} &= q_0^2 - q_1^2 - q_2^2 + q_3^2
 \end{aligned}$$

$$\begin{aligned}
 \text{roll} &= \text{atan2}(R_{31}, R_{33}) \\
 \text{pitch} &= \sin(R_{32}) \\
 \text{yaw} &= \text{atan2}(R_{12}, R_{22})
 \end{aligned}$$

2.1.2 Graphical User Interface

Additionally, a graphical user interface GUI is provided, leveraging PyQt5 [4] and PyOpenGL [5] modules. The GUI manages the main window and handles OpenGL object management. It offers features like port selection and serial communication. The received data is displayed in a textbox within the GUI, facilitating real-time monitoring and analysis. Here is how the GUI is threaded :

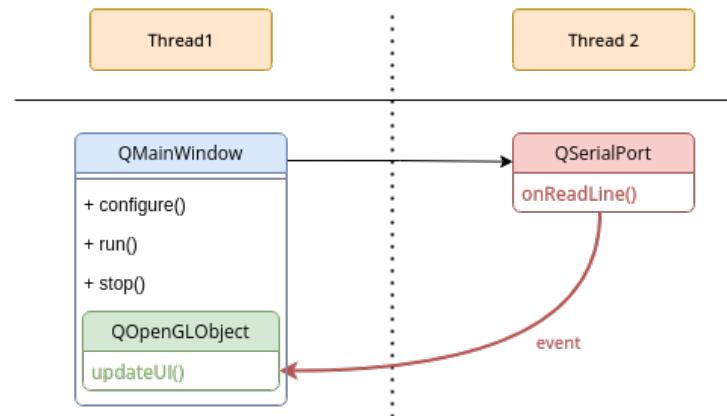

Figure 2.5 – Python GUI threads schematic

The use is rather simple for the communication configuration (cyan box) :

- the port
- the baud rate
- the number of bits per frame
- the number of stop bits
- the parity
- the flow control

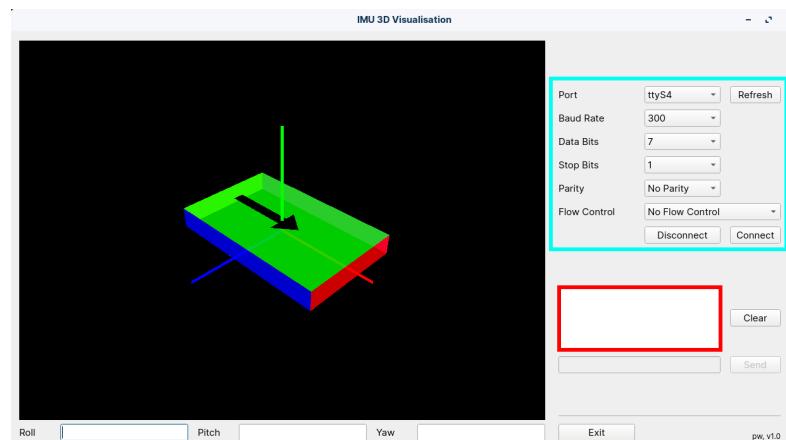

Figure 2.6 – Python GUI window screenshot

Then click on `Connect` to start the serial communication. Every received line appeared in the textBox (red box).

2.1.2.1 Final result

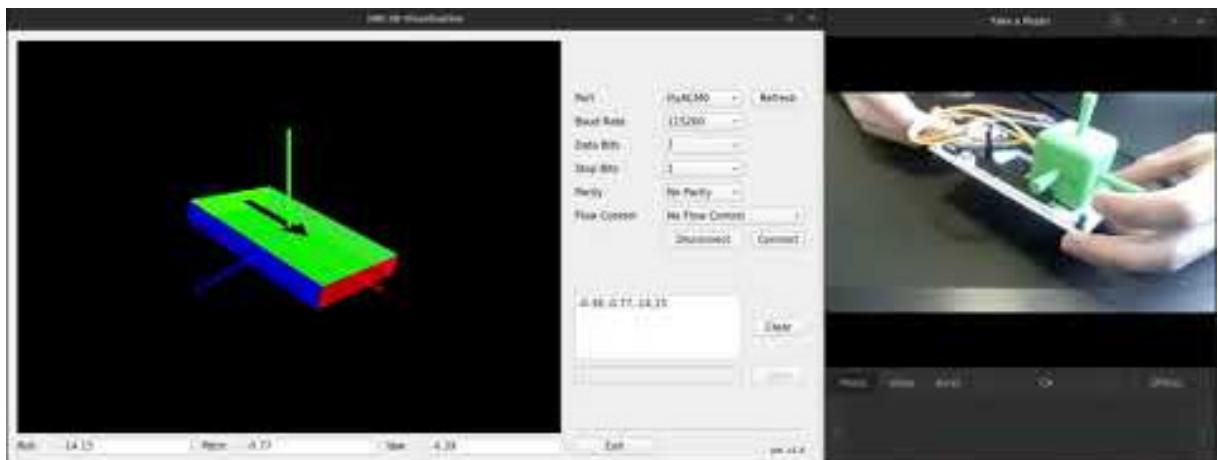

Figure 2.7 – 3D IMU Visualizer demo

2.1.3 Drone blackbox

Drones, or unmanned aerial vehicles, have gained significant popularity and application across various industries. As drones become more advanced and complex, it is crucial to incorporate reliable systems for data logging and analysis. One such system is a blackbox, which serves as a flight data recorder for drones. Here are the reasons of having a blackbox on a drone :

- Flight Data Logging: A blackbox records various flight parameters and sensor data during drone flights. This data can include information such as GPS coordinates, altitude, speed, battery voltage, motor RPM, control inputs, and more. Analyzing this data can provide valuable insights into the drone's performance, diagnose issues, and improve flight characteristics.
- Accident Investigation: In the event of a drone crash or incident, a blackbox can provide crucial data for accident investigation and analysis. It helps in understanding the sequence of events leading up to the accident, identifying any anomalies or failures, and determining the cause of the incident. This information can be used for troubleshooting, improving safety measures, and preventing similar incidents in the future.
- System Optimization: By analyzing the flight data recorded by the blackbox, drone manufacturers and developers can optimize the drone's performance, stability, and

efficiency. They can fine-tune flight control algorithms, evaluate sensor accuracy, and identify areas for improvement in terms of power consumption, aerodynamics, and overall system design.

- Regulatory Compliance: In some countries, drone operations may be subject to regulatory requirements. Flight data recording and analysis can help demonstrate compliance with regulations, such as maintaining safe distances from restricted areas or operating within altitude limits. The recorded data can serve as evidence of adherence to guidelines and regulations set by aviation authorities.

Overall, using a blackbox on a drone provides valuable data for performance analysis, troubleshooting, safety improvement, and compliance with regulations. It allows drone operators, manufacturers, and researchers to gain insights into flight characteristics and make informed decisions for enhancing drone performance and safety.

2.2 LogViewer

The objective of a log viewer application is to facilitate the efficient viewing and analysis of log data generated by systems or applications. This scientific report highlights the key goals and functionality of a log viewer, which includes log visualization, search and filtering capabilities, log analysis and insights, integration with other tools, and customization options.

2.2.1 Sensors tests

Before using any sensors, make sure they work properly, that communication is correct and that measurements are consistent with the reality of the environment. To check all these prerequisites, it's often easiest to use the manufacturer's proprietary software, which is robust, reliable and easy to use.

A few parameters need to be modified to enable the 8 distance sensors and their data to be taken into account by the collision avoidance built-in algorithm.

Here is the final configuration for a minimum effective distance of 3 meters between the drone and obstacles and a maximum effective distance of 5 meters :

	TowerEvo	Description
PRX_ORIENT	0	Default
PRX_TYPE	6	TeraRangerTowerEvo
SERIAL_BAUD	921600	Serial baud
SERIAL_PROTOCOLE	11	Lidar 360 deg
AVOID_ANGLE	1300	Max lean angle
AVOID_BEHAVE	1	Stop when obstacle detected
AVOID_DIST_MAX	5	Max distance avoidance
AVOID_ENABLE	3	Enable drone reaction
AVOID_MARGIN	3	Min distance avoidance

(a) Ardupilot flight controller configuration

(b) Data acquisition acknowledgement

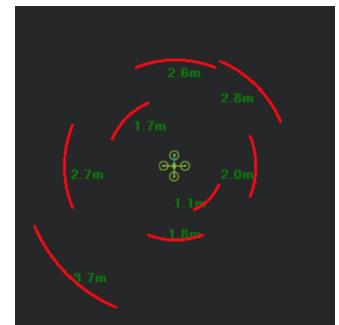

Table 2.1 – Ardupilot configuration & data acknowledgement

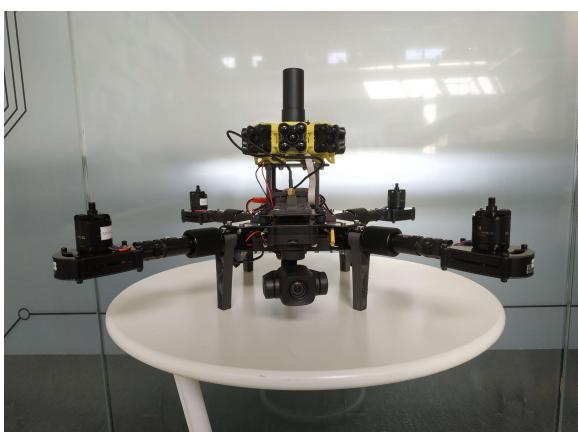

2.2.2 Sensors Integration and drone flight

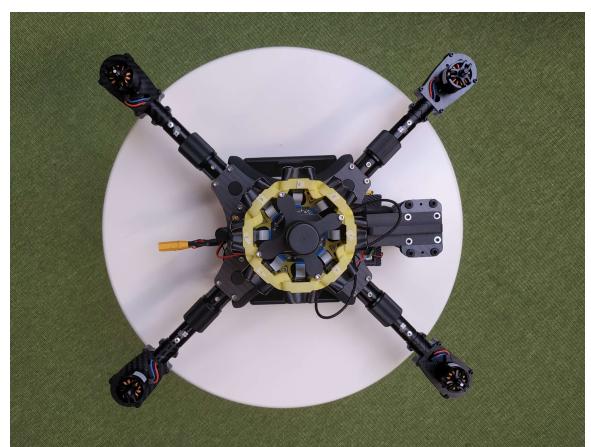

(a) Front left view

(b) Left view

(c) Front view

(d) Top view

Figure 2.8 – Larke Mini drone pictures with 360° degrees LiDAR mounted

The sensors are not integrated into the hull, requiring a large, bulky tower on top of the Larke Mini drone. The integration with the drone is not aesthetic but functional.

Nevertheless the drone successfully achieved its intended mission objectives. Whether it was aerial mapping or surveying, the drone captured distance data effectively. My colleague Sebastian Duus ensured that the drone was in the optimal position for data acquisition, adjusting altitude and camera settings accordingly.

2.2.3 Python Plotly Visualizer

A graphical user interface is provided, leveraging `Plotly` [6] library. The Logviewer import the `.csv` file as data. Here is the `logfile.csv` header :

timestamp(ms)	PRX.D0	PRX.D45	PRX.D90	PRX.D135	PRX.D180
PRX.D225	PRX.D270	PRX.D315	ATT.Roll	ATT.Pitch	ATT.Yaw

Table 2.2 – Plotly logviewer file header

The application is pretty simple : it use the timestamp as main variable to create animated data. I created 3 main plots in th same window :

- the distance sensors plot
- the roll and pitch attitude
- the yaw plot

The most valuable part of this application is the time slider that can be used to go back in time, pause and restart the view. This way the data analysis is easy-to-use.

2.2.3.1 Final result

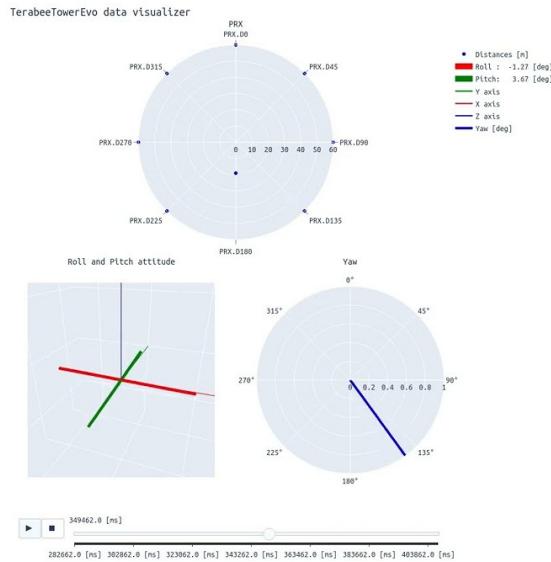

Figure 2.9 – Python LogViewer demo

2.3 Collision avoidance SITL

2.3.1 Environement description

2.3.1.1 Robot Operating System

Robot Operating System 2 (ROS2) is an open-source framework for building robotic systems. It supports distributed systems, allowing communication between different components and nodes running on separate devices. It provides a communication infrastructure for exchanging messages and supports various protocols. ROS2 introduces a quality of service system for controlling communication behavior. It includes real-time capabilities for time-critical applications. It supports multiple programming languages and emphasizes modularity and extensibility. ROS 2 comes with development tools and has an active community and ecosystem. Overall, ROS2 provides a powerful and versatile platform for developing robotic systems. Its distributed architecture, flexible communication infrastructure, real-time capabilities, language support, and extensibility make it a valuable tool for building complex and advanced robots.

2.3.1.2 Gazebo

Gazebo is an open-source 3D simulation environment for robotics. It allows developers to create virtual worlds where they can simulate and test robots. Gazebo provides realistic physics-based simulations, visualizes the environment in 3D, and simulates sensors like cameras and LiDARs. Users can model robots and their surroundings, integrate with the Robot Operating System (Robot Operating System (ROS)), and extend its functionality using plugins. Gazebo has a supportive community and offers a wide range of resources for developers. In summary, Gazebo is a valuable tool for simulating and evaluating robotic systems before deploying them in real-world environments.

2.3.1.3 Ardupilot

Ardupilot is open-source software used for controlling autonomous vehicles like drones. It includes firmware that runs on the vehicle's autopilot hardware, as well as ground control station Ground Control Station (GCS) software for mission planning and monitoring. Ardupilot supports different flight modes, navigation based on waypoints, and telemetry for communication with the vehicle. It is compatible with various hardware platforms and can be customized and extended. Ardupilot is widely used in drones

and other vehicles, and it has a supportive community and extensive documentation. In summary, Ardupilot is a versatile and customizable software suite for autonomous vehicle control.

2.3.2 Built-In Ardupilot collision avoidance

The collision avoidance feature in Ardupilot is designed to enhance the safety and reliability of these vehicles by detecting and avoiding potential collisions with obstacles or other aircraft.

The collision avoidance system in Ardupilot relies on various sensors and algorithms to perceive the environment and make informed decisions about navigation. Some of the key components and techniques used in the Built-In Ardupilot collision avoidance include:

- Sensor Inputs: Ardupilot can interface with different types of sensors, including proximity sensors, LiDAR, sonar, and cameras. These sensors provide information about the surrounding environment and help in detecting obstacles.
- Obstacle Detection: The collision avoidance system processes the sensor data to identify potential obstacles in the flight path. This can include buildings, trees, other aircraft, or any other objects that may pose a risk of collision.
- Path Planning: Based on the environment map and the current position of the vehicle, Ardupilot generates a safe and collision-free path for the aircraft to follow. It considers factors such as obstacle proximity, vehicle speed, and maneuverability to calculate an optimal trajectory.
- Collision Avoidance Algorithms: Ardupilot employs sophisticated algorithms to predict the future movement of obstacles and determine the best course of action to avoid collisions. These algorithms take into account the dynamics of the vehicle and the obstacles.

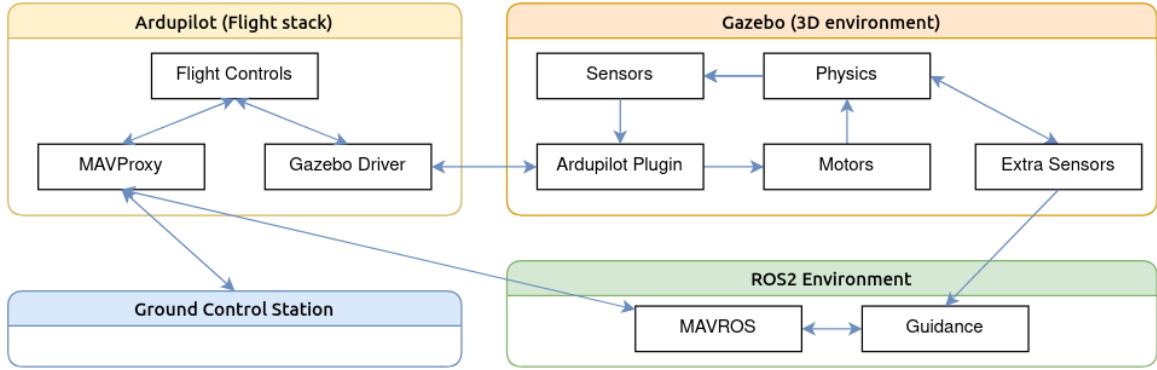

Figure 2.10 – Software-In-The-Loop overall chart[7]

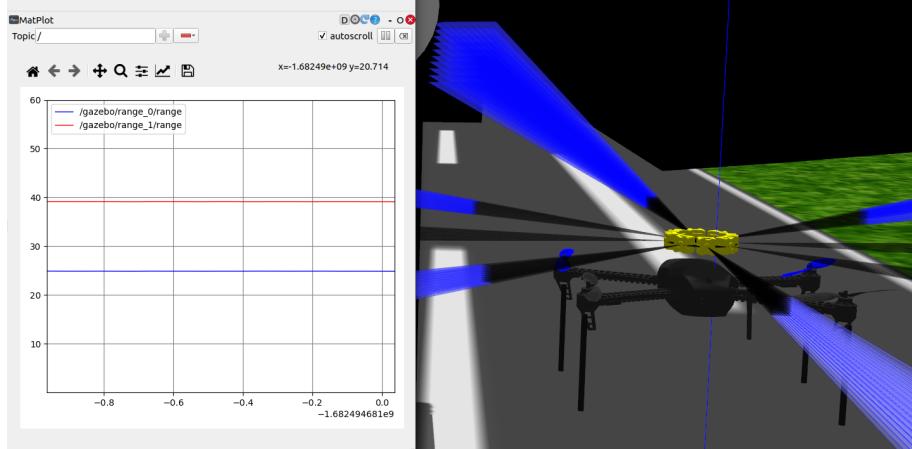

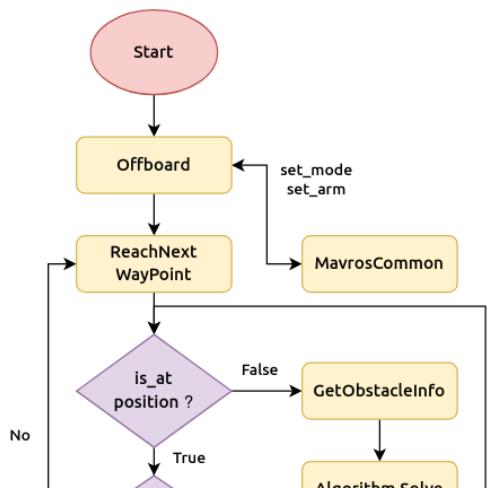

Figure 2.11 – Drone with TowerEvo in Gazebo environment

2.3.3 Collision Avoidance ROS2 Migration

2.3.3.1 ROS1 collision-avoidance description

The aim of this task is to migrate a project from the old version of Robot Operating System (ROS) to the new one ROS2.

The Figure 2.12 represent how the collision avoidance logic is working. It's basically a loop that

covers all the waypoints to reach the final destination. The data acquired by the distance sensors are continuously recorded to enable the algorithm to detect obstacles and change the speed and direction of the drone in real time. As soon as data are acquired, this action chain start : `GetObstacleInfo`, `Algorithm Solve`, `ComputeVelocity` and `PublishVelocity`.

It uses the `potential field method` [8], it's an algorithm used in robotics for motion planning. It represents the environment as a field of attractive and repulsive potentials. The agent is guided towards the goal by attractive potentials and repelled by repulsive potentials generated by obstacles. The agent follows the gradient of the potential field to navigate towards the goal while avoiding obstacles. It is a simple and intuitive approach but can have limitations in complex environments and local minima trapping. Extensions and modifications exist to address these challenges.

2.3.3.2 ROS migration

Migration is a complex process that requires a thorough understanding of the environment in which you're moving and the environment in which you're moving. What's more, programming languages (python here) often evolve between 2 ROS releases, so language errors add to the difficulty. I successfully migrate all the files as expected but unfortunately after 3 weeks working on this tasks, I wasn't able to debug and test the project due to the environment complexity.

My colleagues are way more experienced in ROS2 and migration, so we decided together to stop my part here and let them continue to debug and test the project.

I did, however, learn a lot of principles, such as Quality Of Services (QOS) and Micro Air Vehicle Link (MAVLink) message communication, which are essential for flying robotics projects.

GANTT TASK ORGANIZATION
